CSCE 313-201
Introduction to Computer Systems
Fall 2020

Operating Systems
Dmitri Loguinov
Texas A&M University

August 27, 2020
**Homework #1**

- When running A*  
  - Incorrect # of nodes if weight is integer in \( q = L + \frac{w}{d+1} \)
- Basic BFS and DFS  
  - Order of traversal on this graph?

```
Adjacency list
A: E, D, B
B: A, G
C: E, D, F
D: A, C
E: A, C
F: C, G
G: B, F
```
Homework #1

• Refresh the concept of search
  - Assume an undirected graph $G = (V,E)$
  - Start node $s \in V$
• Maintain two structures
  - Unexplored set $U$
  - Discovered set $D$
• Approach #1:

```java
U.add (s)
while ( U.notEmpty () )
    x = U.removeNextNode () // node to explore
    if ( D.find(x) == true ) // if already explored, ignore
        continue
    N = G.getNeighbors (x) // N is a set of nodes
    if ( N.size() == 0 ) break // exit?
    for each y in N
        U.add (y)
```

Any problems?
Homework #1

- This code fails to actually insert anything into D
- Correct version:

```java
U.add(s)
while ( U.notEmpty() )
    x = U.removeNextNode()
    if ( D.find(x) == true ) // if already explored, ignore
        continue
    D.add(x)
    N = G.getNeighbors(x)
    if ( N.size() == 0 ) break // exit?
    for each y in N
        U.add(y)
```

- Requires huge storage as each node may be pushed into U as many times as there are links to it
  - Not advisable in practice

Any drawbacks?
Homework #1

• Approach #2 inserts a single copy of each node in U:

```
U.add(s); D.add(s);     // s = source node
while (U.notEmpty())
    x = U.removeNextNode();
    N = G.getNeighbors(x);
    if (N.size() == 0) break // exit?
    for each y in N
        if (D.find(y) == false) // has been pushed in U?
            U.add(y)
            D.add(y)
```

Always use this version!

• For most types of non-trivial exploration, approach #2 is far superior to #1
• What if D has a function that combines find/add?
  - Can directly use STL set’s insert() function
Homework #1

• When you find the exit, how far is it from s?
• **Idea:** make U keep track of tuples (nodeID, distance)

```java
U.add (s, 0); D.add (s);
while ( U.notEmpty() )
    t = U.removeNextTuple () // t is a tuple
    N = G.getNeighbors (t.ID)
    if ( N.size() == 0 )
        printf ("Found at distance %d\n", t.distance)
        break
    for each y in N
        if ( D.find (y) == false ) // new node?
            U.add (y, t.distance + 1)
            D.add (y)
```

• Note that U.add() also needs light intensity for bFS/A*
  – See the handout for details
Homework #1

- Reusing the search algorithm
  - Create a base class

```cpp
class Ubase {  
    virtual void Add (uint64 ID, int distance, float intensity) = 0;  
    virtual UnexploredRoom RemoveNextTuple (void) = 0;  
    ...  
}
```

- Inherit four classes

```cpp
class Ubreadth : public Ubase {  
    // implement a queue here  
}
class Udepth : public Ubase {  
    // implement a stack here  
}
```

- Create base pointer to a specific class, then send it to search()

```cpp
Ubase *ptr;  
if (searchType == BFS)  
    ptr = new Ubreadth;  
else if ...  
Search (ptr);  
```

```cpp
Search (Ubase *U)  
{  
    while (U->size() > 0)  
        ...  
}
```
Chapter 2: Book Overview

• Lectures skip chapter 1
  – Mostly 312 background with some examples

• Our goal in chapter 2
  – Understand the motivation for building an OS
  – Introduce basic terminology and history
  – Glance over the main concepts studied later
Chapter 2: Motivation

• Early computers (1940-1950s) did not have an OS
• Programs (called jobs) were loaded manually from punch cards
  – Errors were indicated by lights
  – Printer output signaled successful completion
• Three main problems:
  – Scheduling inefficiency
  – Setup delays
  – Hardware awareness

IBM punch card (invented in 1928)
Chapter 2: Motivation

- Scheduling inefficiencies
  - Sign-up sheet to reserve computer time
  - Wasted resources if job finishes quicker than reserved time
  - Forced termination and repeated visits if taking too long
- Setup delays
  - Loading compiler, source code, libraries, input data, and linking involved mounting tapes and/or card decks
  - If an error occurred, the user had to restart the process
  - Considerable time dedicated to setting up the program to run
- Hardware awareness
  - Programmer had to write directly into device registers in every program, keep track of hardware changes
  - Time wasted on largely irrelevant code development
Chapter 2: Roadmap

2.1 OS objectives and functions
2.2 Evolution of the OS
2.3 Major achievements
2.4 Other developments
2.5 Virtual Machines
2.6 Multi-core considerations
2.7 MS Windows
2.6 Traditional UNIX
2.7 Modern UNIX
2.8 Linux
Evolution of the OS

- Manual job control in the 1940s was known as serial processing
- Extreme inefficiency and inconvenience prompted automation of the process and development of an OS
- Main functions
  - Controls the execution of application programs
  - Provides an interface to hardware
Simple Batch System (1955)

- Early computers were extremely expensive
  - Was important to maximize processor utilization
- With an OS present, user no longer had direct access to CPU or devices
  - Instead, submitted jobs into a FIFO queue that was read and executed by a **monitor**
- When programs were done, they returned control to the monitor

**Job Control Language (JCL)**
- Directives how to run the job (e.g., compiler, input data, job owner)
Simple Batch System

Hardware features

- **Memory protection**
  - Jobs with access violations (e.g., trying to wipe out the monitor) were aborted

- **Timer**
  - Prevented jobs from monopolizing system or infinitely looping
  - Each job had a fixed deadline by which it had to finish

- **Privileged instructions**
  - Execution allowed only by the monitor
  - Prevented jobs from crashing the system or reading unauthorized data (e.g., the next job)
  - Monitor controlled all I/O

- **Interrupts**
  - Were not needed as all I/O was synchronous
Multi-Programmed Batch System (1959)

- Even in batched systems, the CPU was often idle
  - Automatic job sequencing helped reduce the delay *between* the jobs, but not *within* them
  - Reason: I/O devices are slow compared to processor
- **Example**: a job spends 15 ms reading a record from the file, then processes it for 1 ms, and finally writes one record to another file (also 15 ms)
  - What is the CPU utilization?

- This is often called *uni-programming*
Multi-Programmed Batch System

- **Idea**: when one job needs to wait for I/O, the monitor can switch the CPU to another job
  - Various scheduling algorithms are possible
  - Example below uses strict priority scheduling from A to C

<table>
<thead>
<tr>
<th>A</th>
<th>CPU</th>
<th>I/O wait</th>
<th>CPU</th>
<th>I/O wait</th>
<th>CPU</th>
</tr>
</thead>
<tbody>
<tr>
<td>B</td>
<td>wait</td>
<td>CPU</td>
<td>I/O wait</td>
<td>CPU</td>
<td></td>
</tr>
<tr>
<td>C</td>
<td>wait</td>
<td>CPU</td>
<td>wait</td>
<td>CPU</td>
<td>wait</td>
</tr>
</tbody>
</table>

- Interrupts are now needed for monitor to regain control
- This is called **multi-programming** (or **multi-tasking**) and is now the central theme of modern OSes
Example

- At time 0, three jobs are submitted to a monitor in a system with 250 MB of RAM
  - CPU in table means % of time task is not blocked on I/O
  - Assume jobs never conflict on the same I/O device

- Uni-programming

<table>
<thead>
<tr>
<th></th>
<th>Job 1</th>
<th>Job 2</th>
<th>Job 3</th>
</tr>
</thead>
<tbody>
<tr>
<td>CPU</td>
<td>70%</td>
<td>10%</td>
<td>10%</td>
</tr>
<tr>
<td>Duration</td>
<td>5 min</td>
<td>15 min</td>
<td>10 min</td>
</tr>
<tr>
<td>RAM</td>
<td>50 MB</td>
<td>100 MB</td>
<td>75 MB</td>
</tr>
</tbody>
</table>

- Multi-programming
- **Task 1**: completion time of last job in uni-programming?
- **Task 2**: what is the average CPU and RAM utilization?
  - Metric computed over the entire interval
- **Uni-programming**
  - CPU: \((70\% \times 5 + 10\% \times 15 + 10\% \times 10)/30 = 20\%\)
  - RAM: \((20\% \times 5 + 40\% \times 15 + 30\% \times 10)/30 = 33.3\%\)
- **Task 3**: what is the **throughput** of the system?
  - Number of jobs finished per time unit (e.g., 1 hour)
- **Task 4**: what is the **mean response time**?
  - Average delay from job submission to its completion
  - Uniprocessing: \((5 + 20 + 30)/3 = 18.333\text{ min}\)

---

**Example**

<table>
<thead>
<tr>
<th>Job</th>
<th>CPU</th>
<th>Duration</th>
<th>RAM</th>
</tr>
</thead>
<tbody>
<tr>
<td>Job 1</td>
<td>70%</td>
<td>5 min</td>
<td>50 MB</td>
</tr>
<tr>
<td>Job 2</td>
<td>10%</td>
<td>15 min</td>
<td>100 MB</td>
</tr>
<tr>
<td>Job 3</td>
<td>10%</td>
<td>10 min</td>
<td>75 MB</td>
</tr>
</tbody>
</table>
Time Sharing System (1961)

- Batch mode favors long CPU-bound jobs
  - Response time for other tasks may be minutes or hours
- Maximizing CPU utilization does not suit interactive jobs
  - E.g., a text editor cannot wait 3 hours for its turn
- Under time-sharing, CPU is periodically provided to all jobs not waiting for I/O
  - Goal: minimize response delay
- Time divided into slices
  - E.g., 200 ms in early systems, 1-10 ms in modern OSes
- The kernel rotates through all jobs scheduling them to run on the CPU
- Max delay before getting on the CPU
  - Slice * (number of competing jobs – 1)
Time Sharing System

- Comparison

  multi-programmed batch mode

A  CPU
B  wait CPU
C  wait

1 hour

20 ms to process keyboard

Response time of C with 10-ms slices?

First time-sharing OS
  - Compatible Time-Sharing System (CTSS), MIT 1961

All modern OSes are time-sharing
Real-Time System

• In regular OSes, job switching delays are random and depend on the immediate backlog of CPU-bound tasks and their priority
  – Under worst-case scenarios, a job may not receive its turn for many slices

• This presents certain problems in mission-critical applications
  – E.g., car traction control, helicopter missile-guidance system

• Real-time OS (RTOS) provides guarantees on scheduling and interrupt delays
  – Examples include Windows CE, RTLinux, VxWorks
OS Growth

• OSes are complex pieces of software
  – MIT’s CTSS (1961-3): 32,000 machine words
  – IBM’s OS/360 (1964): 1M CPU instructions
  – Multics (1978): 20M CPU instructions

• Later, software was measured in source lines of code (SLOC)
  – Estimates from Wikipedia:

<table>
<thead>
<tr>
<th>Year</th>
<th>OS</th>
<th>SLOC</th>
</tr>
</thead>
<tbody>
<tr>
<td>93</td>
<td>NT 3.1</td>
<td>4M</td>
</tr>
<tr>
<td>94</td>
<td>NT 3.5</td>
<td>7M</td>
</tr>
<tr>
<td>96</td>
<td>NT 4.0</td>
<td>11M</td>
</tr>
<tr>
<td>00</td>
<td>2000</td>
<td>29M</td>
</tr>
<tr>
<td>01</td>
<td>XP</td>
<td>45M</td>
</tr>
<tr>
<td>03</td>
<td>Server 2003</td>
<td>50M</td>
</tr>
</tbody>
</table>

<table>

</table>
Chapter 2: Roadmap

2.1 OS objectives and functions
2.2 Evolution of the OS
2.3 Major achievements
2.4 Other developments
2.5 Virtual Machines
2.6 Multi-core considerations
2.7 MS Windows
2.6 Traditional UNIX
2.7 Modern UNIX
2.8 Linux
**Major Achievements**

- Impossible to deal with OS complexity without certain systematic ways of managing resources, jobs, and users

- Major advances in the development of operating systems (layout of the book):
  - Processes and threads (ch. 3-4)
  - IPC (inter-process communication) and synchronization mechanisms (ch. 5-6)
  - File systems (ch. 11-12)
  - Memory (RAM) management (ch. 7-8)
  - Scheduling and resource allocation (ch. 9-10)
  - Information protection and security (ch. 14-15)

covered in this class
